What's New in the Oracle To MSSQL?

Turning an Oracle database into a Microsoft SQL server database is what Oracle to MSSQL is capable of doing. Just about everything about this program revolves around its ability to take the database you're trying to move to a Microsoft SQL server, by running a few simple commands and allowing you to do everything from that point on. Overview: If you want to quickly and easily extract data from many different flat files into a single SQL table with a single INSERT statement, this article explains how to do it. The first step is to create an INSERT statement for each source file. Then, you have to copy the INSERT statement into a regular.sql file, and then drag that into Excel. Finally, you will create a Visual Basic or VBScript function that accesses the function. For this example, I will use Visual Basic, but the VBScript method should work with the same results. Each INSERT statement should look like this: Step 2: Save the INSERT statement to a.sql file Copy each INSERT statement into a.sql file, using the same name as the source file (do not use.sql because it is a reserved name for SQL Server) Step 3: Run the SQL script Open a command prompt or shell window and run the SQL file. Step 4: Create a Visual Basic or VBScript function Create a Visual Basic or VBScript function. See how to create a function in the VBScript section of this article. The function would look like this: Custom function Function GetFileName(fileText) Dim f, f2, col, i, ss, r Set f = CreateObject("Scripting.FileSystemObject") f.CreateTextFile "C:\Users\mssql.txt" f2 = "C:\Users\mssql.txt" r = Split(f2, "\") Set col = Sheets(1).Range("B3:B11").Value ss = split(fileText, vbTab) For i = 1 to UBound(ss) r(i) = ss(i) Next GetFileName = r End Function Step 5: Run the script Run the V
